

IN THE ABSTRACT:

Please amend the Abstract as indicated below:

Methods and apparatus are disclosed for transmitting data, such as
 5 biometric data or Internet telephone data, in a packet network. Packets are split and
 interchanged prior to transmission across a packet network, such that packets that reach
 their destination may be processed, even in the presence of lost or delayed packets.
 Packets of biometric data, such as fingerprints, retinal scans or voice characteristics, or
sampled voice packets are split, and optionally interchanged prior to transmission. If
 10 some packets are lost or delayed, while some of the packets reach their destination and
 provide sufficient data for user identification, then the user may be authenticated without
 requesting the retransmission of the lost or delayed data. ~~Sampled voice packets are split,~~
~~and optionally interchanged prior to transmission.~~ If some packets are lost or delayed,
 while some packets reach their destination, then the received speech samples may be
 15 reproduced without requesting the retransmission of the lost or delayed data. 160 A
~~packet splitter splits framed data into a number of packets. For example, the framed data~~
~~is split into two packets with the first packet containing k frames having odd indexes and~~
~~the second packet having k frames having even indexes. If both packets arrive at a~~
~~destination point, they can be integrated back into the framed data comprised of the~~
 20 ~~continuous string of frames, $f_1, f_2, f_3, \dots, f_N$. Otherwise, if a packet was lost or~~
~~significantly delayed, the data can be recovered from the single received packet using, for~~
~~example, smoothing techniques, such as spline extrapolation, for the lost packets with~~
~~even indexing.~~
